

# Web Python Lesson 1: HTTP and APIs

[vanderbi.it/py](http://vanderbi.it/py)

Steve Baskauf

# APIs vs. web scraping

- An **API (application programming interface)** is designed by the information provider to make structured data available to web users
- APIs usually make information available in JSON
- **Web scraping** is necessary when the information provider doesn't intend or doesn't bother to make structured data easily available.
- Web scraping is only practical if there is consistent format within or among web pages in a site.
- Web scraping extracts information from HTML

# URI vs. URL

- A **URI** is a **U**niform **R**esource **I**dentifier
- A URI is a globally unique identifier for anything
  
- A **URL** is a **U**niform **R**esource **L**ocator
- A URL is a subset of URIs that will actually retrieve a file.
  
- When I say URI, you can generally think "URL"

# HTTP protocol

Hypertext Transfer Protocol (HTTP), used to carry out an interaction across the Internet. mediated by. Retrieving information using HTTP GET is called "dereferencing a URI". (People also say "resolving" a URI.)

Image from Clipart Panda

## Client software

(a.k.a. the "machine")

In this case, the client is a web browser. It displays the returned body as a web page.

HTTP **GET**

`http://dbpedia.org/resource/Bonobo`

**Accept:** text/html

*asking for a web page*

Image from Clipart Kid

## Web server

HTTP **Status:** 200 OK

**Body:**

```
<?xml version="1.0" encoding="UTF-8" ?><!DOCTYPE html PUBLIC "-//W3C//DTD XHTML+RDFa 1.0//EN" "http://www.w3.org/MarkUp/DTD/xhtml-rdfa-1.dtd"><html xmlns="http://www.w3.org/1999/xhtml" xmlns:dbpprop="http://dbpedia.org/property/" ...
```

# Dereferencing a URI in a browser

- Paste the URI from the Jupyter notebook:

`http://bioimages.vanderbilt.edu/pages/contributors.htm`  
into a browser and request.

# Pieces of HTTP

- Request type: GET, POST, and others
- Status code (response from server): 200, 30x, 404
- Response headers from server:
  - Content-Type (media type being sent)
  - Content-Length (bytes)
  - Date
- Body (text from server)

- Paste the URI from the Jupyter notebook:

`http://bioimages.vanderbilt.edu/pages/contributors.htm`  
into Postman and Send.

# Exploring HTTP with Postman

The screenshot shows the Postman interface for a GET request to `http://dbpedia.org/page/Bonobo`. The interface is annotated with red arrows and text:

- request type**: Points to the `GET` dropdown menu.
- URL**: Points to the request URL `http://dbpedia.org/page/Bonobo`.
- Accept: header value**: Points to the `text/html` value in the Headers tab.
- status code**: Points to the `200 OK` status in the response summary.
- response body**: Points to the XML response content in the Body tab.

KEY	VALUE	DESCRIPTION

  xml:Lang="en"
>
  <!-- header -->
  <head profile="http://www.w3.org/1999/xhtml/vocab">
    <meta charset="utf-8" />
    <meta http-equiv="X-UA-Compatible" content="IE=edge" />
```

What we are sending to the server

What the server is sending back to us

# Exploring HTTP with Python

- Run the first script on the Jupyter notebook

# Turn off automatic redirects

The image shows a screenshot of the Postman application interface. At the top, there is a navigation bar with "My Workspace" and "Invite" buttons. Below this, a toolbar contains several icons, including a wrench icon for settings. A red arrow points from the text "click settings wrench" to this wrench icon. The main area displays an "Untitled Request" with a GET method and a URL: `http://vocab.getty.edu/download/?jsonld?url=http://vocab.getty.edu/page/tgn/7017496`. Below the URL bar are tabs for "Params", "Authorization", "Headers (8)", "Body", "Pre-request Script", "Tests", and "Settings". The "Settings" tab is active, showing a "SETTINGS" dialog box with a close button (X). The dialog has tabs for "General", "Themes", "Shortcuts", "Data", "Add-ons", "Certificates", "Proxy", "Update", and "About". The "General" tab is selected, showing two columns of settings. The "REQUEST" column includes "Trim keys and values in request body" (OFF), "New Code Generation Mode" (OFF), "SSL certificate verification" (ON), "Always open requests in new tab" (OFF), "Always ask when closing unsaved tabs" (ON), "Language detection" (Auto), "Request timeout in ms (0 for infinity)" (0), "Max response size in MB (0 to infinity)" (50), and "Automatically persist variable values" (OFF). The "HEADERS" column includes "Send no-cache header" (ON), "Send Postman Token header" (ON), "Retain headers when clicking on links" (OFF), "Automatically follow redirects" (OFF), and "Send anonymous usage data to Postman" (ON). A red arrow points from the text "turn off" to the "Automatically follow redirects" toggle. The "USER INTERFACE" column includes "Editor Font Size (px)" (12), "Two-pane view" (OFF), "Show icons with tab names" (ON), "Variable autocomplete" (ON), and "Open Launchpad" (ON).

click settings wrench

SETTINGS

General Themes Shortcuts Data Add-ons Certificates Proxy Update About

**REQUEST**

- Trim keys and values in request body  OFF
- New Code Generation Mode  OFF
- SSL certificate verification  ON
- Always open requests in new tab  OFF
- Always ask when closing unsaved tabs  ON
- Language detection Auto
- Request timeout in ms (0 for infinity) 0
- Max response size in MB (0 to infinity) 50
- Automatically persist variable values  OFF

Enabling this will persist the current value of variables to the initial value at the end of every request execution.  
[Learn more about variable values](#)

**HEADERS**

- Send no-cache header  ON
- Send Postman Token header  ON
- Retain headers when clicking on links  OFF
- Automatically follow redirects  OFF
- Send anonymous usage data to Postman  ON

**turn off**

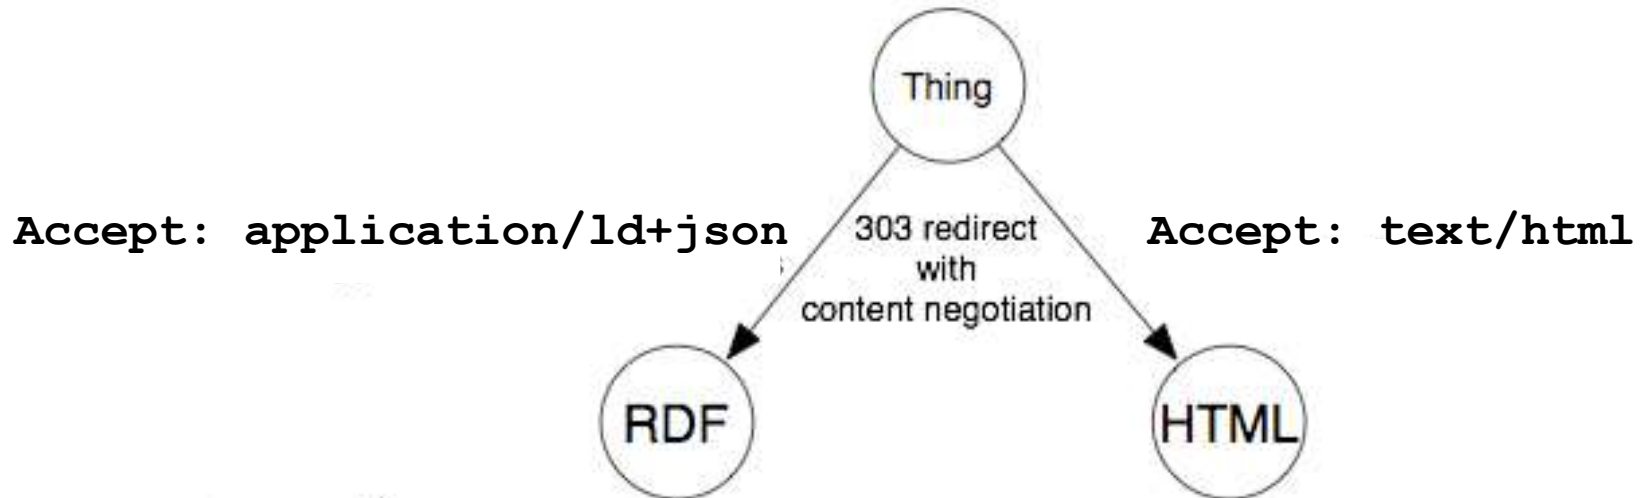

**USER INTERFACE**

- Editor Font Size (px) 12
- Two-pane view  OFF
- Show icons with tab names  ON
- Variable autocomplete  ON
- Open Launchpad  ON

# Content negotiation: diagram

- We can send request headers to the server with information about what we want it to send
- An example is an **Accept** header for our preferred media type

`http://dbpedia.org/resource/Bonobo`

`http://dbpedia.org/data/Bonobo.jsonld`

`http://dbpedia.org/page/Bonobo`

# Exploring HTTP with Postman

The screenshot shows the Postman interface for a GET request to `http://dbpedia.org/page/Bonobo`. The request type is `GET`. The `Accept` header is set to `text/html`. The response status is `200 OK`. The response body is XML-RDF data.

**Annotations:**

- request type:** Points to the `GET` dropdown menu.
- URL:** Points to the request URL `http://dbpedia.org/page/Bonobo`.
- Accept: header value:** Points to the `text/html` value in the Headers tab.
- status code:** Points to the `200 OK` status in the response summary.
- response body:** Points to the XML-RDF data in the response body.

KEY	VALUE	DESCRIPTION
<input checked="" type="checkbox"/> Accept	text/html	
Key	Value	Description

```

# Content negotiation: Postman

- Set URL to `http://dbpedia.org/resource/Bonobo`
- Set Accept header to `text/html` and Send
- Examine status code, Location response header, and body
- Set URL to `http://dbpedia.org/page/Bonobo` and Send
- Examine status code, Location response header, and body
- Repeat starting with Accept header `application/ld+json`

# Postman settings

- Turn automatic redirects back on
- Unless something goes wrong, we don't care that much about how we get to the final URL

# Content negotiation with Python

- Run the second script in the Jupyter notebook
- Not every website or API supports **Accept** headers
- Sometimes the desired media type is requested directly as part of the URL
- Usually the server correctly identifies the **Content-Type** that it's sending (but not always)

# Using data from GitHub

- A lot of data are now available from GitHub
- Example: heights of U.S. presidents rendered as a table:  
[https://github.com/jakevdp/PythonDataScienceHandbook/blob/master/notebooks/data/president\\_heights.csv](https://github.com/jakevdp/PythonDataScienceHandbook/blob/master/notebooks/data/president_heights.csv)
- To use in Python, we need the raw data. Click the Raw button, then copy the URL.
- Example script in Jupyter notebook.

# What's an API?

- An API is a website that provides access to structured data (usually JSON, sometimes XML)
- An **endpoint** is a URL that returns data about a particular kind of thing (known as a "**resource**").
- A simple API may have only one endpoint.
- More complex APIs may have many endpoints that allow you to get information about a variety of things
- It's impossible to know what an endpoint does without a "developer guide" or "API reference".

# API etiquette

- Do not harvest the entire dataset. Ask the provider for a **data dump** if you want the whole thing.
- Do not **repeatedly hit** the API at high speed. Use the `.sleep()` function from the `time` module to limit the rate of your requests, e.g.

`time.sleep(1)`

for a one second delay.

- Most APIs will require you to use **paging** to receive a reasonable amount of data in one call.
- Abusing an API often will result in you being **blocked** at least for a time.
- Test your script in a **sandbox** (if one is available) before using the real API.

# International Space Station API

- This simple API only does one thing: return the latitude and longitude of the current position of the ISS.
- The script uses the `.json()` method to turn the JSON response text into a Python data structure.
  - Notice that valid JSON requires keys and values to be in double quotes.
  - The Python data structure in this case is a dictionary, which can have keys and values in single or double quotes.

# Options for sorting through JSON

## 1. VS Code

- paste the JSON string
- save with a `.json` file extension
- right click, select **Format Document**

## 2. JSON Editor Online (good if file is huge)

- <https://jsoneditoronline.org/>
- past JSON on left
- click rightward arrow and expand or collapse

## 3. Use `json.dumps()` in your Python code

- **indent** argument sets indentation spacing
- **sort\_keys** alphabetizes keys within JSON objects
- See code example in Jupyter notebook

# Putting data into a GitHub Gist

- Easiest way to give access to data for others to use in Python
- GitHub account required
- After creating the Gist, click the raw button
- Copy the URL to use in your code
  
- Technical note: all GitHub raw files are served as **Content-Type = text/plain** regardless of actual file type
- Some applications will have problems with incorrectly identified media types.

# Putting data in a GitHub Gist

# For next week:

- Create a GitHub account if you don't already have one.
